At fixed logical volume W, fragmentation $B_f(A)$ controls the boundary-resource penalty

Filled cube

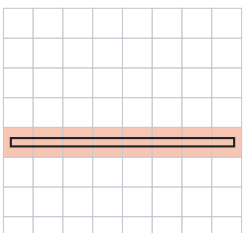

$B_f(A) = O(W^{2/3}/b^2 + 1)$

few partial coarse cells

Thin slab, thickness $h < b$

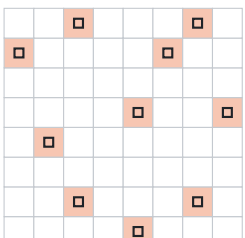

$B_f(A) = \Theta(W/(hb^2))$

same W, every cell partial

Isolated sites

$B_f(A) = W$

same W, one partial cell per site

filled coarse cell partially filled cell (counted in $B_f(A)$) region A
